

Technical Briefing – Economic Assessment of Water pumping Options.

Introduction.

Economic considerations are important when comparing alternative pumping methods. In many cases hydrological, or climatological factors will limit the kind of pumping system that can be used. Where alternatives exist, the evaluation of the alternatives must include both economic and technical analysis.

There are 2 concepts to be understood before taking any economic assessment:

Payback period: the length of time required for the initial investment to be repaid by the benefits gained.

Life Cycle costs: the sum of all costs and benefits associated with the pumping system over its lifetime (or over a selected period of analysis), expressed in present day money. This is called the Present Worth or the Net Present Value of the system. For the system to be worthwhile, the benefits must be greater than the costs.

The most complete approach to **economic appraisal** is to use the life cycle cost analysis because all future expenses are then taken into account.

In this method, all the future costs and benefits are calculated in 'present day' values. Because the value of money changes with time, it would be unrealistic to add up the future costs as they stand. Future costs and benefits must be discounted to their equivalent value in today's money, called their 'Present Worth'. To do this, each future cost is multiplied by a factor dependent on a discount rate and the year when the expenditure is incurred.

Example: a discount rate of 10% per year would mean that in real terms, it makes no difference to a person whether he has 100\$ now or 110\$ in a year time. Conversely, a cost of 110\$ in a year from now, would have a 'present worth' of 100\$.

Calculation of the Present Worth.

The calculation of PW involves the use of a discount rate which reflects the opportunity cost of capital.

It should be stressed that the change in the value of money expressed by the discount rate is NOT the change due to general inflation, but the difference in return between an investment one makes and another that one chooses not to make.

Values of discount rate that are used for other projects in the country concerned can usually be taken as a guide. High discount rates mean that a low value is put on future costs and benefits, so money available at present is of more value.

For a payment of Cr(\$) to be made in the future, the Present Worth (PW) is found by multiplying the payment Cr by a factor Pr:

$$\text{(formula 1.1) } PW = Cr * Pr, \text{ with } Pr = 1/(1+d)^n$$

With time for the payment (n, in years) and discount rate (d) as main variables (note: if d=10%, d=0.1 in the formula 1.1)

Note: Different inflation rates could be used for different products (eg pumps, solar panels, invertors, etc); however since this would need an in-depth knowledge of market sectors and price evolution for different components, it will be considered that the general inflation rate in the country apply to all products equally (or in other words, the differential inflation between that of each product and the general inflation rate used to calculate the discount rate is zero). This is often taken as an approximation to simplify LCCA analysis.

Discount rate (d): also called Real Interest Rate, is calculated subtracting the real inflation rate to the nominal interest rate, both data to be taken for the country where we are considering the activity to take place (example: if the lender is receiving 9% from a loan and the inflation rate is 8%, then the Real Interest Rate= Nominal interest rate – Real inflation rate = 9 – 8 = 1).

Real Interest Rate per country can be found at http://data.worldbank.org/indicator/FR.INR.RINR?year_high_desc=false or in Annex A. It is advised to use an average of Real Interest Rates for the last 5 years as Discount Rate, as this will represent better this rate.

In case there is no information for your country in Annex A, the discount rate adopted should be close to the lending interest rate provided by commercial banks in your location.

So overall the Total Present Worth would be,

(formula 1.2) Total PW = I + $\sum_{n=1}^N Cr * [(1/(1+d)^n)]$,with I= capital investment.

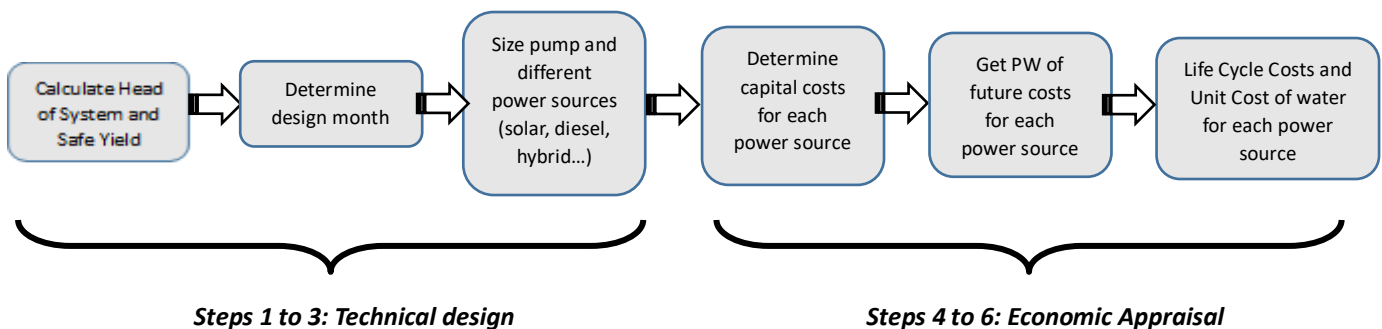

With I= initial or capital costs, Cr= O&M costs + Overhaul costs + Replacement costs, and N=length of analysis period in years

Economic Appraisal using Life Cycle costing for Water Pumping.

For each pumping system on which we are going to perform a life-cycle cost analysis by bringing cost to their Present Value, we need to identify all the initial and future costs. These can be generally divided into the following 3 categories:

- Initial capital costs (including installation).
- Operation & Maintenance (minor and major services and fuel).
- Overhaul and Replacement of equipment during lifetime.

Step-by-step Procedure for a Techno- Economic Appraisal.

Step 1: it is assumed that WASH officers are familiar with H,Q calculations.

Step 2: for diesel based systems, the design month is the month with highest water demand. For Solar is the month that requires the largest array size for the estimated demand in that particular month. If demand is estimated to be constant through the year, then the design month is the one with lowest solar irradiation.

Step 3: it is assumed WASH officers are familiar with sizing of pumps and different power sources (generators, stand alone solar PV systems, hybrid systems and others). For Solar systems, a computer based system should be preferably used.

Step 4 to 6: the data required for the last 3 steps are given in the below table,

Economic	Period of analysis (typically all systems are taken to the longest lifespan of any of the components, which is 25 years for solar panels).
	Discount rate (=Nominal interest Rate – Inflation Rate)
	Relative inflation rate (typically zero)
Cost of each component	Capital cost
	Annual O&M, Overhaul, Replacement costs
	Manpower cost, cost of diesel, grid power cost or other power source costs as relevant
Technical	Lifetime of each component

Annex A: Table of Real Discount Rate for the last 5 years to 2015.
